Introduction

This is the 83nd annual report of the International Ice Patrol (IIP). It contains information on Ice Patrol operations, environmental conditions, and ice conditions for the 1997 IIP season. The U.S. Coast Guard conducts the Ice Patrol in the North Atlantic under the provisions of U.S. Code, Title 46, Sections 738, 738a through 738d, and the International Convention for the Safety of Life at Sea (SOLAS), 1974. The IIP is supported by 17 member nations (Appendix A). It was initiated shortly after the sinking of the RMS TITANIC on April 15, 1912 and has been conducted yearly since that time.

Commander, International Ice Patrol (CIIP) is under the operational control of Commander, Coast Guard Atlantic Area. CIIP directs the Ice Patrol from its Operations Center in Groton, Connecticut. IIP receives iceberg location reports from ships and planes transiting its patrol area and conducts aerial Ice Reconnaissance Detachments (ICERECDETs) to survey the southeastern, southern, and southwestern regions of the Grand Banks of Newfoundland for icebergs. IIP analyzes ice and environmental data and employs an iceberg drift and deterioration model to produce twice-daily iceberg warnings, which are broadcast to mariners as ice bulletins and facsimile charts. IIP also responds to requests for iceberg information. IIP's ICERECDETs were based in St. John's, Newfoundland, Canada during the 1997 season.

The cover graphic shows the hand-drawn ice chart based on observations made by the U.S. Revenue Cutter SENECA during the ice seasons 1913 and 1914.

Vice Admiral Kent H. Williams was Commander, Atlantic Area until May, 1997, when he was relieved by Vice Admiral Roger T. Rufe, Jr. CDR Ross L. Tuxhorn was Commander, International Ice Patrol until July, 1997, when he was relieved by Commander Stephen L. Sielbeck.

Summary of Operations, 1997

The 1997 IIP year (October 1, 1996 - September 30, 1997) marked the 83rd anniversary of the International Ice Patrol, which was established February 7, 1914. IIP's operating area is enclosed by lines along 40°N, 52°N, 39°W and 57°W (Figure 1).

IIP's first preseason aerial ICERECDET of the year departed on January 26. The 1997 IIP season was opened on March 03 and from this date until July 31, 1997 an ICERECDET operated from Newfoundland approximately every other week. The season officially closed on August 14, 1997.

IIP's Operations Center in Groton, Connecticut analyzed the iceberg sighting information from the ICERECDETs, ships, Canadian Ice Services (CIS) sea ice/iceberg reconnaissance flights, and other sources. Air reconnaissance, consisting of Coast Guard (IIP), Other Air Recon, and CIS was the major source of iceberg sighting reports this season, accounting for 61.8% of the

icebergs sighted in 1997 (Table 1). Ships provided 27.3% of the iceberg sightings received by IIP in 1997. Their continued active participation indicates the value that they place on IIP's service. In 1997, 285 ships of 45 different nations provided ice information to IIP. This demonstrates that the number of nations using IIP services far exceeds the 17 member nations underwriting IIP under SOLAS 1974. Appendix B lists the ships that provided iceberg sighting reports, including reports of stationary radar targets. In Appendix B, a single report may contain multiple targets.

The largest contributor of air reconnaissance reports was Provincial Airlines Limited (PAL). Their reports accounted for nearly all of the category "Other Air Recon" on Table 1. PAL is a private company that provides aerial reconnaissance services for the Canadian Department of Fisheries and Oceans (DFO) year round, and for CIS June through December. DFO flights, which are designated to monitor the activities of fishing vessels, frequently carry them to areas with

high iceberg concentrations. The next largest contribution to the air reconnaissance total was from IIP ICERECDETs. IIP flights concentrate on defining the boundaries of the iceberg distribution. These are typically areas of low iceberg concentration. Table 2 shows the important contribution of IIP reconnaissance in determining the limits of all known ice (LAKI). The attributes of the individual icebergs that set the LAKI are described in Appendix C. BAPS sightings are icebergs detected north of 52°N primarily by CIS reconnais-

sance. These are passed to IIP by CIS when icebergs are predicted to have crossed into the Ice Patrol operating area. CIS provided IIP with iceberg information obtained during sea ice reconnaissance flights and a few flights dedicated solely to iceberg reconnaissance.

During 1997, the IIP Operations Center received a total of 4829 target sightings within its operations area which were entered into IIP's drift model. This is about 20% more than the 3902

target sightings during 1996. The 4829 targets entered into IIP's drift model do not represent all of the targets reported to IIP. Sightings of targets outside IIP's Area of Responsibility (AOR) were not entered into the model. Most of these were far to the north of IIP's AOR, in areas not covered by IIP's model. Coastal iceberg sightings were also screened, and only those with the potential to drift into the trans-Atlantic shipping lanes were entered into the IIP model.

Table 3 includes icebergs detected south of 48°N plus the number of icebergs which were predicted to have drifted across 48°N for each month of 1997. During the 1997 ice year, an es-

timated 1011 icebergs drifted south of 48°N; whereas, during 1996, 611 icebergs had drifted south of 48°N.

IIP classifies the severity of the ice seasons based on the historic iceberg counts of its entire 83 year history. Ice years with fewer than 300 icebergs crossing 48°N are defined as light ice years; those with 300 to 600 crossing 48°N as moderate; and those with more than 600 crossing 48°N as extreme. Thus, 1997 was in the "extreme" classification, but was an average year for iceberg conditions compared to the SLAR years of 1983-97 where the average is 1093.

The 1997 season was the fifth year that IIP used its iceberg Data Management and Prediction System (DMPS). This system, which is nearly identical to the iceBerg Analysis and Prediction System (BAPS) used at the Canadian Ice Centre, Ottawa, combines an iceberg drift model with a deterioration model. The drift model uses wind, ocean current, and iceberg size data to predict the movement of all icebergs entered into DMPS. This model uses a new historical current data base (Murphy, Viekmán and Channel, 1996), which is modified weekly using satellite-tracked ocean drifting buoy data, thus taking into account local, short-term, current fluctuations. Murphy and Anderson (1985) described and evaluated the drift model. The iceberg deterioration model uses daily sea surface temperature and wave height information from the U.S. Navy Fleet Numerical Meteorology and Oceanography Center (FNMOC) to predict the melt of icebergs. Anderson (1983) and Hanson (1987) described the IIP deterioration model in detail.

In Ice Season 1998, IIP will use the Iceberg Data Management and Prediction System (IDMPS). IDMPS will run on a faster UNIX system which will interface with a Windows NT based Geographical Information System (GIS) in order for IIP to more efficiently process and predict iceberg drift and deterioration information. The fundamental aspects of the model will not change.

Thirteen satellite-tracked ocean drifting buoys were deployed to provide current data for

IIP's iceberg drift model during the 1997 season. The buoys are similar in design to the World Ocean Circulation Experiment (WOCE) and were equipped with surface temperature sensors and a drogue centered at 50 meters. The data were distributed in near real time via the Global Telecommunications System. Drift data from the buoys are presented in the IIP 1997 Drifting Buoy Atlas, which is available upon request. IIP also provided weekly drifting buoy sea surface temperature (SST) and drift histories to the Canadian Meteorological and Oceanographic Centre (METOC) in Halifax, Nova Scotia and the U.S. Naval Atlantic Meteorology and Oceanography Center (NLMOC) in Norfolk, Virginia for use in water mass and SST analyses.

During the 1997 season, IIP successfully deployed 170 Air-deployable eXpendable BathyThermographs (AXBTs), which measure temperature with depth and transmit the data back to the aircraft. Temperature data from the AXBTs were sent to the METOC Halifax, NLMOC, and FNMOC for use as inputs into ocean temperature models.

The AXBTs are deployed as part of a cooperative program between Canadian Meteorological Centre (CMC)/METOC, which provides the probes, and IIP, which deploys the probes and distributes the data. This cooperation benefits both organizations. The temperature data improves the FNMOC products which are used in IIP's iceberg deterioration model and are a valuable source of information for METOC's regional oceanographic analysis.

On April 15, 1997, IIP paused to remember the 85th anniversary of the sinking of the RMS TITANIC. During an ice reconnaissance patrol, two wreaths were placed near the site of the sinking to commemorate the more than 1500 lives lost.

.....

Iceberg Reconnaissance and Communications

During the 1997 Ice Patrol year, 112 aircraft sorties were flown in support of IIP. Of these, 54 were transit flights to St. John's, Newfoundland, IIP's base of operations and 54 were ice observation flights made to locate the southwestern, southern, and southeastern limits of icebergs. Four logistics flights were required to support and maintain the patrol aircraft. Tables 4 and 5 show aircraft use for the 1997 ice year.

IIP's aerial ice reconnaissance was conducted with radar equipped U.S. Coast Guard HC-130H aircraft. The HC-130H aircraft used on Ice Patrol are based at Coast Guard Air Station Elizabeth City, North Carolina. Although they were not used in 1997, IIP has used HU-25B aircraft in past years. These aircraft are stationed at Air Station Corpus Christi, Texas and are available for use. However, the areal extent of the iceberg distribu-

tion in 1997 required the use of the long range HC-130H aircraft.

Since the Grand Banks region is very oceanographically and meteorologically dynamic, the visibility is notoriously poor. Therefore, IIP relies heavily on the AN/APS-135 Side Looking Airborne Radar (SLAR) and the AN/APS-137 Forward Looking Airborne Radar (FLAR). SLAR is the primary detection sensor while FLAR is the primary identification sensor, providing the ability to distinguish targets as icebergs or vessels. These sensors allow IIP aircraft to use a 30 nautical mile track spacing when searching for icebergs. Details on SLAR are in Robe et al. (1985) while details on FLAR are in Trivers and Murphy (1995).

IIP schedules aerial iceberg surveys every other week rather than every week. This

TOTAL	54	319.9

is due to the ability of the SLAR and FLAR to detect and differentiate icebergs in all weather, combined with use of the iceberg drift and deterioration computer model to track icebergs in-between sightings.

Both the number of flight hours and sorties were greater in 1997 than in 1996. The total number of flight hours increased from 449.1 hours in 1996 to 483.1 in 1997. The number of sorties increased from 103 in 1996 to 112 in 1997. These increases reflect the greater extent of the geographic limits of the icebergs to the east of Flemish Cap and the Grand Banks during 1997.

Each day during the ice season IIP prepared and distributed ice bulletins at 0000Z and 1200Z to warn mariners of the southwestern, southern, and southeastern limits of icebergs. U. S. Coast Guard Communications Station Boston, Massachusetts, NMF/NIK, and Canadian Coast Guard Radio Station St. John's Newfoundland/VON were the primary radio stations responsible for the dissemination of the ice bulletins. In addition, the ice

bulletins and safety broadcasts were delivered over the INMARSAT-C SafetyNet via the AOR-W satellite. Other transmitting stations for the bulletins included METOC Halifax, Nova Scotia/CFH, Canadian Coast Guard Radio Station Sydney/VCO, and Radio Station Bracknell, UK/GFE.

IIP also prepared a daily facsimile chart, depicting the limits of all known ice, for broadcast at 1600Z and 1810Z daily. In addition, the facsimile chart was placed on Comsat Corp's INMARSAT-A FAXMAIL Server for receipt at sea. U. S. Coast Guard Communications Area Master Station Atlantic/NMN assisted with the transmission of these charts. Canadian Coast Guard Radio Station St. John's Newfoundland/VON and U. S. Coast Guard Communications Area Master Station Atlantic/NMN also provided special broadcasts as required.

As in previous years, International Ice Patrol requested that all ships transiting the area of the Grand Banks report ice sightings, weather, and sea surface temperatures via Canadian Coast Guard Radio Station St. John's/VON, U. S. Coast Guard Communications Area Master Station Atlantic/NMN, or INMARSAT-C or -A using code 42. Response to this request is shown in Table 6. Appendix B lists all contributors. IIP received relayed information from the following sources during the 1997 ice year: Canadian Coast Guard Marine Radio Station St. John's/VON; Canadian Coast Guard Vessel Traffic Centre/Ice Operations St. John's; Ice Centre Ottawa; Canadian Coast Guard Marine Communication and Traffic Services Halifax, Nova Scotia/VCS; ECAREG Halifax, Nova Scotia; U. S. Coast Guard Communications Master Station Atlantic, Chesapeake, Virginia; U. S. Coast Guard Atlantic Area Command Center; and U. S. Coast Guard Automated Merchant

Vessel Emergency Response/Operations Systems Center, Martinsburg, WV. Commander, International Ice Patrol extends a sincere thank you to all stations and ships which contributed reports. The vessel providing the most reports was the HMCS Montreal, a Canadian Forces vessel.

In addition, Ice Patrol receives land based lighthouse reports from stations along the coast of Newfoundland. The lighthouses providing these reports are listed in Table 7.

Discussion of 1997 Ice Conditions

Background

This section presents a brief discussion of the sea ice and iceberg distribution prior to and during the 1997 season. While IIP monitors many environmental conditions near the Grand Banks, by far the two most important to iceberg population are the flow of the off-shore branch of the Labrador Current and the distribution of sea ice.

The offshore branch of the Labrador Current is the main mechanism transporting icebergs south to the Grand Banks and the North Atlantic shipping lanes (Figure 2). Its relatively cold water keeps the deterioration of icebergs to a minimum. Ice Patrol uses satellite tracked drifters to monitor the variability in the Labrador current. The tracks of the 13 drifters used in 1997 are described in the Drifting Buoy Atlas which is available upon request.

Sea ice protects the icebergs from wave action, the major agent in iceberg deterioration. If sea ice extends to the south and over the Grand Banks of Newfoundland, the icebergs will be protected longer as they drift south. When the sea ice edge retreats in the spring, large numbers of icebergs may be left behind in the vicinity of the Grand Banks. If the time of retreat of the sea ice edge is delayed by below-normal air and sea surface temperatures, the icebergs will be protected from melt longer and be expected to survive to drift farther south. In these cases, a longer than normal ice season can be expected. Less southerly sea ice extent or above normal air and sea surface temperatures may result in a shorter season.

Sea ice can impede the transport of ice-

bergs. The degree depends on the concentration of the sea ice and the size of the icebergs. The greater the sea ice concentration, the greater the effect on iceberg drift. The larger the iceberg, the less sea ice affects its drift.

The 1997 Season

Figures 3 to 10 compare the sea ice edge during the 1997 ice year to the mean sea ice edge. The mean sea ice edges were taken from Cote (1989) and represent a 25 year average (1962-1987). The ice edge (sea ice concentration $\geq 1/10$) is taken from the daily Ice Analysis from the Ice Centre, Ottawa.

Figures 11 to 21 show the Ice Patrol Limits of All Known Ice (LAKI) and the daily sea ice edge on the 15th and the last day of each month during the ice season. The ice edge is taken from the Ice Centre, Ottawa FICN2 daily product. The edge plotted is a coarse numeric representation of the daily IceAnalysis. These figures show the distribution of all icebergs and radar contacts tracked by IIP's model at the indicated times. Numerals are given for clarity for those one-degree squares where six or more targets were located.

The following is a discussion of the ice conditions, comparing those ice conditions observed and modeled in 1997 with the twenty-year IIP climatological LAKI described by Viekman and Baumer (1995).

December through February

Through December and January, sea ice growth along the Labrador coast and in East Newfoundland waters appeared to be slower

than normal (Figures 3-4). February and March showed a reversal in the preceding month's sea ice growth pattern (Figures 5-6). The sea ice extent exceeded normal conditions during this period and reached as far south as 46°N in the vicinity of the Grand Banks. At the end of February, 10 icebergs were south of 48°N. The reported LAKI (Figure 11) approximated the climatological median position for 15 March, thus triggering the start of the Ice Patrol Season on 3 March.

March

Throughout the month of March, a tongue of sea ice extended eastward to approximately 46°N, 47°W (similar to sea ice conditions of 1995), implying significant surface circulation towards the east (Figure 6). As seen with these conditions in the past, the reported LAKI positions for March (Figures 11-12) extended to an extreme eastward longitude of 39°W. There were 475 icebergs south of 48°N and the southern extent of the LAKI at the end of March was 42°N.

April

For the first half of the month, the eastern sea ice tongue receded, but remained extended to 49°N, 49°W (Figure 7). Later in the month, the sea ice rapidly melted and the edge receded toward the Labrador-Newfoundland coastlines. IIP's LAKI was reported near the 25th percentile climatological LAKI for the month of April (Figures 13-14). There were 162 icebergs south of 48°N in April.

May

Sea ice melting occurred at a normal rate. However, remnants persisted along the coast of Newfoundland (Figure 8). The reported LAKI on 31 May (Figure 16) reached the 25th percentile to the east and the median climatological LAKI to the south. There were 238 icebergs south of 48°N in May.

June

The sea ice edge retreated above 52°N (Figures 9-10). The IIP LAKI (Figures 17-18) approximated the median climatological LAKI in the east and fell between the 75th percentile and the median to the south. There were 80 icebergs south of 48°N in June.

July

The reported LAKI (Figure 19) approximated the median climatological LAKI to the east reaching 44°W. To the south, the LAKI reached an extreme position of 41°30'N on 15 July. By 30 July, the LAKI had retreated to the median around 46°N. There were 43 icebergs south of 48°N in July (Figure 20).

August

The LAKI had retreated to 48°N by mid-August (Figure 21) while there were 3 icebergs south of 48°N. The Ice Patrol Season closed on 14 August.

Appendix C

Limit-Setting Iceberg Report for 1997 Season

CDR Stephen Sielbeck and MST2 L. Scott Howell

Introduction

International Ice Patrol's mission is to identify the Limits of All Known Ice (LAKI) and to transmit this information to mariners at sea. During the ice season, the key element of IIP operations is to conduct reconnaissance patrols to determine the location of icebergs that establish the LAKI.

The LAKI is based on all known iceberg and sea ice information and represents the extent of iceberg danger in the vicinity of the Grand Banks of Newfoundland. From Newfoundland, the line marks the southwestern, southern and southeastern limits of the iceberg region, and ends at an intersection point with latitude 52°N. Over the last twenty years, at its extremes, the LAKI has extended in the northwestern Atlantic Ocean as far south as latitude 39°N and in the east to longitude 37°W.

Limit setting icebergs are those icebergs that form the vertices of the LAKI. International Ice Patrol in recent years has collected data to learn more about these important icebergs. Analysis of this data has indicated the large relative contribution of sightings from IIP reconnaissance flights in this critical area near the limits.

The information pertaining to the limit setting icebergs is important as a measure of effectiveness of IIP's surveillance efforts in locating the iceberg hazard. It is IIP's goal to continuously improve its mission performance by effectively locating the icebergs that constitute the LAKI and accurately provide this information to ships to enable them to avoid encountering icebergs.

Data Collection

Limit setting icebergs were categorized as eastern, southern and western by the side of the LAKI "polygon" where they occurred. For the majority of cases, the three categories of icebergs were distinct populations. The few exceptions were when icebergs drifted from the southern limit to the eastern limit and, in those instances, the iceberg's designation was changed accordingly.

Data on the limit setting icebergs were gathered daily from the output of the Iceberg Data Management and Prediction System (DMPS). Icebergs were recruited as limit setters either from the 1200Z Ice bulletin list of "icebergs not in area of many bergs" or from iceberg sightings by the various source at or near the LAKI. Each day, the icebergs in the limit setter database checked to ascertain any resights or deletions these changes were recorded. The following information was determined for each of the designated limit setting icebergs:

1. DMPS iceberg number
2. Days on plot in DMPS model.
3. Days as a limit setting iceberg.
4. Source of sighting when entered in limit setter database, and any subsequent resighting source.
5. Location on LAKI - (West, South, East)
6. Method of deletion

Collection of data on a given limit setting iceberg ended when it was deleted from DMPS by standard IIP criteria. There are two ways

by which IIP removes an iceberg from DMPS.

1. The iceberg deterioration model predicted the iceberg has melted (Anderson, 1983).
2. The area around the predicted position of the iceberg has been thoroughly searched either through visual or double radar coverage.

Discussion

During the 1997 season, 178 icebergs determined the LAKI. Table 1 lists the sources of the limit setting icebergs when they were initially sighted, or first entered into the iceberg drift model, and when they were last sighted in the area of the LAKI. As in the previous season (Tuxhorn and Krein, 1996), the table shows that IIP reconnaissance was the primary contributor of icebergs that eventu-

Table 1
Sources of LAKI Icebergs

Sighting Source	Initial Report (% of Total)	Final Report (% of Total)
Coast Guard (IIP)	41	42

Ships	18	22
BAPS	6	4
Other	12	10

ally established the LAKI and the major sighting source of the icebergs prior to melting completely and removal from the model.

Table 2 shows the initial sighting sources for the three categories of icebergs: western, southern and eastern limit setters. Examina-

tion of the numbers reveals that IIP provided the largest number of iceberg reports on all three sides of the LAKI. Ships reported limit setting icebergs along the east, south and west regions. Iceberg reports from Canadian AES (GCFR), Other Air Recon (GPCD),

Table 2
Initial Iceberg Sighting Sources With Respect to LAKI Region

Sighting Source	LAKI Icebergs			Combined Count
	West	South	East

BAPS	0	0	13	13
National Ice Center (NIC)	0	3	13	16
Other	0	0	4	4
				178

and BAPS and Other Sources were concentrated along the eastern limits.

The size distribution of the limit setting icebergs, as reported by the final sighting source, is displayed in Table 3. A third of the sightings were reported as 'general sized icebergs', which is the unspecified size used for most

Table 3
Size Distribution of LAKI Icebergs

Size Category	% of Total
Growler	8
Small	12
Medium	25
Large	17
Very Large	5
General	33

part to indicate icebergs detected by IIP radar surveillance.

Again this season, the study showed that IIP's melt model is very important as a tool for maintenance of the LAKI. From Table 4, 69% of the limit setters were deleted after reaching 150% melt. Non-detection of icebergs during reconnaissance patrols accounted for 31% of the deletions, of the icebergs that comprised the LAKI. The reader is directed to the IIP Organization and Procedures Manual

Table 4
Deletion Method of LAKI Icebergs

<u>Method</u>	<u>% of Total</u>
150% Melt	69
200% Radar Coverage	23
Visual Recon Coverage	8

bergs which pass south of 52°N latitude or are detected in the IIP operations area melt before they ever approach near the LAKI.

This season's study reinforced a finding of the 1996 study, that approximately half of the limit setting icebergs are detected by IIP reconnaissance. In 1996, 61% of the limit setting icebergs were initially detected by IIP patrol flights conducting reconnaissance patrols near the limits. For the 1997 season, IIP patrols accounted for 41% (Table 1) of the initial sightings of limit setting icebergs. Most of these detections occurred near the LAKI, which means these icebergs either make it through the IIP operations area (from 52°N to LAKI) undetected or are created in the region near the LAKI. If the latter is considered, it suggests that the splitting of icebergs into "pieces" as they journey south, and especially in the vicinity of the LAKI, is an important process of their deterioration. Regardless of how they get there, the fact that these icebergs are found at the LAKI gives impetus for IIP to remain vigilant in this region.

(CIIPINST M5400.1) for the policies pertaining to deletion of icebergs from the model.

The results from this work have yielded a better understanding of the contributing surveillance sources and the final fates of the limit setting icebergs. In the 1997 Season, 4839 icebergs (including resights) were entered in the IIP iceberg drift models, of which 178 were used to set the LAKI. For comparison, in the 1996 Season, 3902 icebergs were entered in the IIP iceberg drift model, of which 110 became limit setters. Assuming data from these two years are typical, the great majority of ice-

Appendix D

Analysis of IIP Reconnaissance Results

CDR Stephen L. Sielbeck and MST2 Tristan T. Krein

Introduction

International Ice Patrol provides a seasonal service of iceberg patrols when the presence of icebergs threatens the North Atlantic shipping routes near the Grand Banks of Newfoundland. Information concerning iceberg conditions near the limits of all known ice is collected primarily through air surveillance conducted by IIP.

IIP reconnaissance data, iceberg reports from other sources, ocean currents and relevant environmental data are used by iceberg drift and deterioration computer models. Every twelve hours, the numerical models estimate iceberg positions and determine the limit of all known ice (LAKI). This limit is broadcast as ice bulletins and facsimile charts to ships crossing the Atlantic Ocean between Europe and North America. Data collected from each of the 1997 ice season patrol flights, when used with similar data from the 1995 and 1996 seasons (Table 1), provide a useful gauge of the effectiveness of IIP reconnaissance efforts and the accuracy of drift and deterioration models.

Data Collection

Data on iceberg detections, iceberg deletions, and changes to the LAKI from iceberg patrols in 1997 are shown in Table 2. The iceberg detection numbers (icebergs, growlers, and radar targets) were taken from the flight messages reporting results of each iceberg reconnaissance flight. There were fifty five (55) patrol flights in 1997. The number of icebergs deleted as a result of each patrol was

derived from the process of merging the patrol information into the iceberg computer database. Iceberg deletions from the database involve duty watch officer decision making within parameters set down in "Standing Orders For IIP Operations Center Duty Personnel" (CIIP Instruction M3120B). Changes to LAKI, calculated in square nautical miles, were determined by simple comparison of the limits before and after reconnaissance information were merged into the model.

Discussion

The iceberg population in the vicinity of the Grand Banks varies annually with respect to numbers, density and distribution. The limits of all known ice are normally defined by a small number of icebergs. The average number of iceberg detections per patrol in 1997 was 14 and the average number of deletions was 8 icebergs. The variation in iceberg sightings from one patrol to the next is a function of the geographic location of the patrol area; patrols near LAKI usually yield small counts while patrols farther north result in higher numbers of detections. Deletions occur when an area is surveyed with acceptable visibility or radar coverage and the patrol does not find any ice near predicted iceberg positions.

The change of ocean area enclosed by LAKI resulting from reconnaissance patrols in 1997 is depicted in Figure 1. Increases in area indicate iceberg detections close to or outside LAKI, conversely, decreases result from an absence of icebergs at predicted locations. Of 55 patrols, 22 reduced and 5 increased the area defined by LAKI. The re-

maintaining 18 flights neither increased nor decreased the area enclosed by LAKI. This does not imply that the limits were accurate on those dates because several of those patrols were special purpose flights to deploy drifting buoys or to verify iceberg density at interior locations. A few patrols were incomplete, due to sensor or aircraft problems, and had no impact on the limits. On two occasions IIP reconnaissance detected ice outside LAKI. The most dynamic regions, and the area most important to shipping, were the southern limits of all known ice. Typically, the southern limits had the highest priority for each ice reconnaissance detachment's patrol efforts.

IIP strives to maintain accurate LAKI, neither underestimating nor overestimating the threat

icebergs pose to mariners. Effective reconnaissance and proficient model performance are expected to produce only nominal changes in LAKI. The 1997 reconnaissance data suggest that the drift and deterioration models are conservative, since, in most cases, the flights reduced the area enclosed by LAKI. On the other hand, there were six occasions in 1997 when ice was observed outside IIP's published LAKI. While this is a small error (~2%) when compared to the 330 ice bulletins produced by IIP in 1997, it is significant because mariners were unaware of these dangerous icebergs. As a result, we do not wish to make our models less conservative. The data emphasize the importance of regular, effective reconnaissance in maintaining accurate LAKI.
